

Epoprostenol (Flolan pH12)

PRESENTATION:	500mcg powder and solvent for infusion (50mls).
INDICATION:	Inhibitor of platelet aggregation in haemofiltration circuit. Use when intravenous heparin is not suitable or is contraindicated. e.g. patient is HIT positive, patient is at risk of bleeding from heparin, platelets less than $50 \times 10^9/l$. (please refer to CVVHD anticoagulation guidelines on the intranet)
DOSE AND ADMINISTRATION:	<ul style="list-style-type: none"> Withdraw 10mls of the solvent into a sterile syringe. Inject the 10mls into the vial containing 500micrograms epoprostenol. Shake vial gently to ensure contents have completely dissolved. Draw up the resulting epoprostenol solution into a syringe. Inject the entire contents into the vial containing the remaining solvent. Mix well. This is now the concentrated solution – 10,000 nanograms/ml. This solution has a 12 hour expiry, and should be stored at room temperature (25°C). Withdraw 15mls of the concentrated solution (10,000nanograms/ml) into a 20ml syringe. Attach the 0.22micron filter provided*. Withdraw 35mls of sodium chloride 0.9% into a 50ml syringe. Filter the 15mls of concentrated solution into the 50ml syringe containing 35mls of sodium chloride 0.9% over approximately 20 seconds. Mix well. This will produce a concentration of 3000 nanograms/ml. <p>*Use a separate 0.22micron filter each time a syringe of 3000 nanograms/ml epoprostenol is prepared.</p>
CONCENTRATION:	Final solution 3000 nanograms/ml
STABILITY:	<p>Both 3000 nanograms/ml and 10,000 nanograms/ml solutions are stable for 12 hours at room temperature (25°C).</p> <p>Due to 12 hour expiry of both solutions, two vials of epoprostenol 500mcg will be required for a 24 hour period regardless of infusion rate.</p>

**ADDITIONAL
INFORMATION:**

Due to the high pH (12), epoprostenol (Flolan pH 12) MUST be administered through a dedicated lumen of a central line. It must never be given peripherally or through the anticoagulant port of the CVVHD machine.

- Epoprostenol dose is titrated against the patient's blood pressure, to maintain a systolic or mean pressure as dictated by clinical targets.
- Starting dose is 1 nanogram/kg/minute i.v. during the priming period, increased by 1 nanogram/kg/minute every 5-10 minutes, up to **4 nanograms/kg/minute**.
- If the filter clots on 4 nanograms/kg/minute, consider increasing to 5 nanograms/kg/minute after consultation with medical staff.
- If priming is required to ensure adequate circulating volumes of epoprostenol, commence the infusion centrally for 15-30 minutes prior to CVVHD starting.

Preparation and administration materials containing polyethylene terephthalate (PET) and polyethylene terephthalate glycol (PETG) may become damaged when using the epoprostenol solution prepared with solvent pH 11.7-12.3, and must not be used.

Infusion Guidelines

Infusion rate may be calculated using the following:

$$\text{Infusion rate (ml/min)} = \frac{\text{Dosage (nanogram/kg/min)} \times \text{body weight (kg)}}{\text{Concentration of infusion (nanogram/ml)}}$$

Epoprostenol 3000 nanograms/ml (diluted solution)								
Body weight (kg)								
Dosage nanograms/kg/ min	30	40	50	60	70	80	90	100
1	0.60	0.80	1.00	1.20	1.40	1.60	1.80	2.00
2	1.20	1.60	2.00	2.40	2.80	3.20	3.60	4.00
3	1.80	2.40	3.00	3.60	4.20	4.80	5.40	6.00
4	2.40	3.20	4.00	4.80	5.60	6.40	7.20	8.00
5	3.00	4.00	5.00	6.00	7.00	8.00	9.00	10.00
Infusion rates in ml/hour								

Monitoring

- Monitor blood pressure. Hypotension may occur. If excessive hypotension occurs during administration, senior medical advice should be sought and the dose may need to be reduced or the infusion discontinued.
- Monitor heart rate. Epoprostenol may either increase or decrease heart rate.

Common side effects include:

- Facial flushing, warm sensation, headaches, abdominal discomfort, nausea, vomiting, thrombocytopenia, jaw pain, tachycardia and bradycardia.
